Type: Oral presentation

## Testing the Millisecond Pulsar Scenario of the Galactic Center Gamma-Ray Excess With Very High Energy Gamma-Rays

Thursday, 29 October 2015 17:15 (20 minutes)

Recent analyses of Fermi Large Area Telescope data show an extended GeV  $\gamma$ -ray excess on top of the expected diffuse background in the Galactic center region, which can be explained by annihilating dark matter (DM) or a population of millisecond pulsars (MSPs). We propose observations of very high energy (VHE)  $\gamma$ -rays to distinguish the MSP scenario from the DM scenario. GeV  $\gamma$ -ray MSPs should release most of their energy to the relativistic e± wind, which will diffuse into the Galaxy and radiate TeV  $\gamma$ -rays through inverse Compton scattering and bremsstrahlung processes. By calculating the spectrum and spatial distribution, we show that such emission is detectable with the next generation VHE  $\gamma$ -ray observatory, the Cherenkov Telescope Array (CTA), under reasonable model parameters. It is essential to search for multi-wavelength counterparts to the GeV  $\gamma$ -ray excess in order to solve this mystery in the high-energy universe.
